

## Steps to Create a Python Package

---

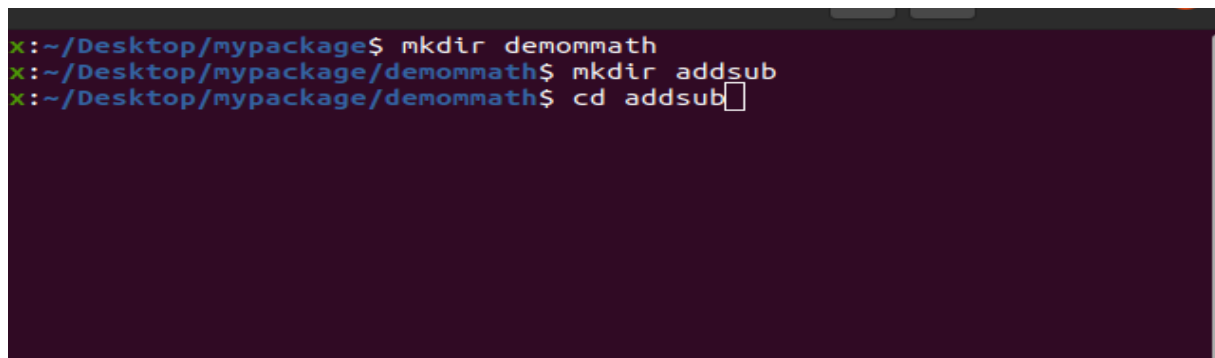

### # Creating a Python Package

Creating a Python package involves organizing your code into a directory structure and adding special files. Here's a step-by-step guide to help you create a simple Python package:

#### ## Step 1: Create the Package Directory

Start by creating a new directory for your package. This directory will contain your package modules and other necessary files.

```
```bash
mkdir "Name of directory" #example : mkdir demommath
cd "Name of directory"    # cd demommath
```
```

A terminal window with a dark purple background. The prompt is 'x:~/Desktop/mypackage\$'. The first command is 'mkdir demommath', the second is 'mkdir addsub', and the third is 'cd addsub'. Each command is preceded by a green 'x' and followed by a green prompt character. The cursor is at the end of the third command.

```
x:~/Desktop/mypackage$ mkdir demommath
x:~/Desktop/mypackage/demommath$ mkdir addsub
x:~/Desktop/mypackage/demommath$ cd addsub
```

#### ##Step 2: Create Sub Directory

```
mkdir "Name of Sub directory" # mkdir addsub
```

#### ## Step 3: Create Modules

Inside your package directory, create Python modules (`.py` files) that will be part of your package. For example:

```
```python
# demommath/addsub/addas.py
def func1():
    print("Function 1")

# demommath/multidiv/md.py
def func2():
    print("Function 2")
```

...

[illegible]

### ## Step 4: Create `\_\_init\_\_.py`

In the main package directory, create an `__init__.py` file. This file can be empty, or you can use it to initialize your package.

```
``python
#demommath/___init___py
```

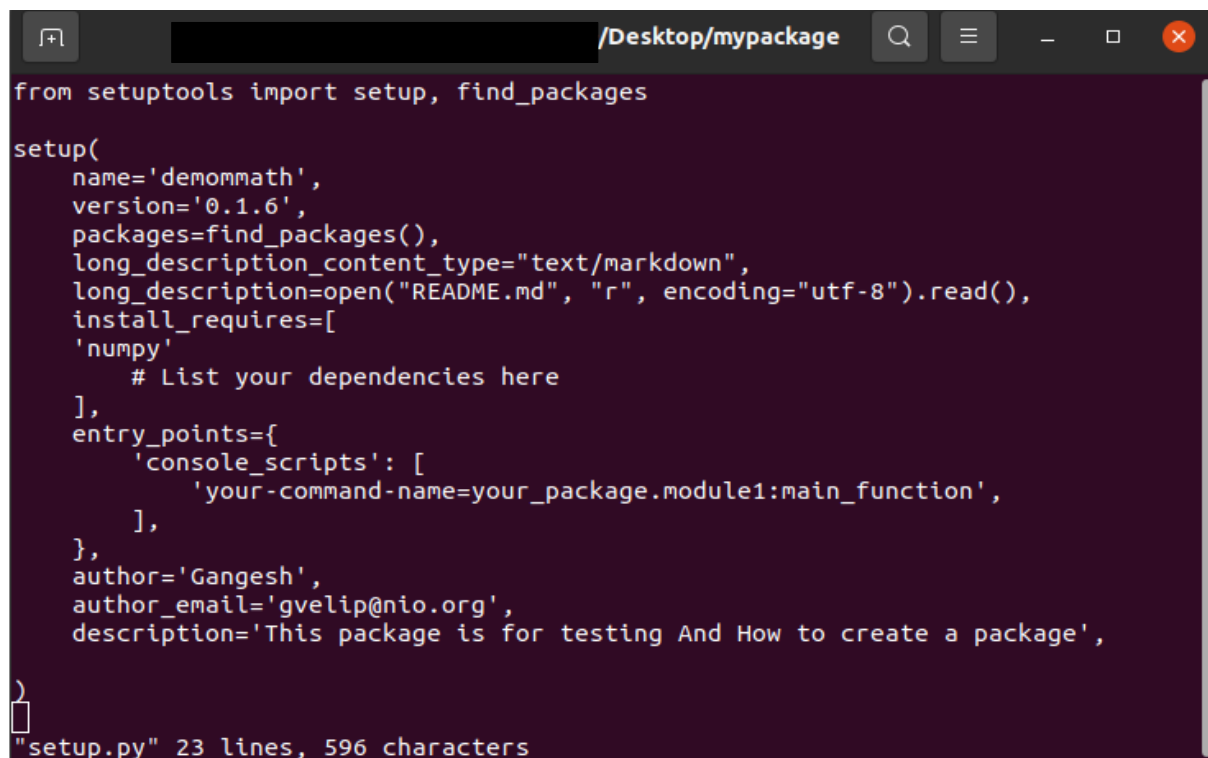

In each package sub directory, create an `__init__.py` file. This file can be empty, or you can use it to initialize your package.

```
# demommath/addsub/__init__.py``
```

To initialize package in the sub directory

```
``python
#demommath/addsub/__init__.py
from .addas import add
from .addas import subtract``
```

```
from setuptools import setup, find_packages

setup(
    name='demommath',
    version='0.1.6',
    packages=find_packages(),
    long_description_content_type="text/markdown",
    long_description=open("README.md", "r", encoding="utf-8").read(),
    install_requires=[
        'numpy'
        # List your dependencies here
    ],
    entry_points={
        'console_scripts': [
            'your-command-name=your_package.module1:main_function',
        ],
    },
    author='Gangesh',
    author_email='gvelip@nio.org',
    description='This package is for testing And How to create a package',
)

"setup.py" 23 lines, 596 characters
```

### ## Step 6: Install setuptools

If you don't have `setuptools` installed, install it using:

```
```bash
pip install setuptools
```
```

### ## Step 7: Create a README.md file

This text file contains all the information about how to use the package.

### ## Step 8: Build and Install the Package

Navigate to the directory containing your `setup.py` file and run the following commands:

```
```bash
python setup.py sdist
```

This Step creates build and dist directories.

To install locally,

```
pip install dist/demommath-0.1.4.tar.gz
```

```
...
```

## ## Step 9: Verify

Now, you should be able to import and use your package in other Python scripts or environments:

```
``python
>>>from demommath import addsub
>>>addsub.add(2,8)
10
``
```

This is a basic example. Depending on your package's complexity, you may need to add more details to your `setup.py` file. Refer to the [setuptools documentation] (<https://setuptools.pypa.io/>) for more options and customization.

```
---
```

Feel free to customize the package structure and `setup.py` according to your project's requirements.
